Object of the Experiment (Block Letter)

TO DETERMINE THE FREQUENCY OF A.C. MAINS BY USING A SONOMETER APPARATUS REGUIRED ii. Non-magnetic wire iii Stepdown transformer iv. Horse shoe magnet v. A set of slotted weights vi. Weight hanger viii. Micrometer screw When A.C. is passing through the conductor, since the current direction reverses periodically, the direction of force also periodically and hence, the vibrates. Since the current flowing is alternating, the wire vibrates with a freual to the frequency of A.C. By the wire length of the vibrating wire segment this frequency can be made equal to the natural frequency of the wire ségment. Then the resonance takes place and the wire vibrates with manimum amplitude. At this stage, the length of the wire segment is called the resonating length and it increases with increase in the mass of the suspended weights. In the presence of magnetic field, current carrying conductor experiences a magnetic field force

ollage

which is periodic. The frequency of forced vibration is same as the frequency of a.c.
bration is same as the frequency of a.c.
